TITLE

Electron Spin Resonance in Some Sandwich Type Chromaromatic Compounds.
(Elektronnyy paramagnitnyy rezonans v nekotorykh khromaromaticheskikh soyedineniyakh sandvichevogo stroyeniya -Russian)

PERIODICAL

Doklady Akad.Nauk SSSR, 1957, Vol 115, Nr 1, pp 118- 121 (U.S.S.R.)

ABSTRACT

In recent times increased interest was devoted to the study of the mentioned compounds of the ferrocene type, $(Fe(C_5H_5)_2)$, the ferrocene ion and analogous molecules with aromatic addenda. In spite of a great number of papers on this subject, there hitherto exists no general theory which might explain the present data on the "sandwich" structure of these molecules. Their formation and steadiness cannot be fully explained by the generally accepted conception of valence. The data obtained indicate that in the majority of compounds of this type the linkage of addenda with the complex-forming atoms is of a covalent character. This is especially indicated by magnetic measurements. According to the latter these materials are either diamagnetic or they possess a magnetic momentum which corresponds to one, two or at most three non-paired electrons. The ion salts of these metals of such compounds by the method of electronic paramagnetic resonance (called EPR in the following) have hitherto been described in publications. The present paper gives measurements of the EPR spectra of the following compounds: $Cr(C_6H_6)_2J$ (I), $Cr(C_6H_5)_2J$ (II) and $Cr(C_6H_5 - C_6H_5 - C_6H_5)_2OC_6H_5$ (III). The static magnetic susceptibility

Card 1/3

Electron Spin Resonance in Some Sandwich Type Chromaromatic Compounds. 20-1-32/54

of these materials corresponds to a single- non-coupled electron. The presence of a hydrogen-overrefined structure of the absorption line in solutions of the materials II and III can be explained in two ways. 1. The non-coupled electron and the positive charge of the complex are located on the chromium atom. The estimation made on the basis of this assumption shows that the density of the non-coupled 3d-electron on the positions of the hydrogen atoms of the aromatic rings is sufficient to effect an "overrefined" cleavage of the EPR spectrum. 2. The non-coupled electron and the positive charge are located on the aromatic addenda of the complex. The overrefined structure is in this case due to the interaction of the non-paired π -electron of the aromatic ring with the hydrogen atoms of this ring. The extent of cleavage, the number of components and the ratio of their intensities are in this case dependent on the distribution of electron density on the addenda molecule. The following facts speak in favor of the first assumption: a) presence of the anisotropy of the g-factor in the materials I and II, b) the value of the g-factor is less than that of a free electron. The true picture of density distribution of the non-coupled electron is probably a superposition of the two extremum cases mentioned above. (2 illustrations, 2 Slavic references.)

TITLE: On the mechanism of extracting nonmetallic impurities from steel drops in
slag

SOURCE: AN SSSR. Izv. Metallurgiya i gornoye delo, no. 2, 1964, 26-30

TOPIC TAGS: ShKh-15 steel, ANF-6 slag, EI-736 steel, impurity, extraction

ABSTRACT: The authors investigated the passing of ShKh-15 steel drops through a
layer of fused ANF-6 slag and its purification from non-metallic impurities. The
amount of large impurities decreased during this process to a greater degree than
did the fine impurities. Impurities larger than 10 μ , present in the initial metal,
disappeared completely. This cannot be the result of flotation, since the metal of
the mobile drop was intensely agitated. It was experimentally shown that the con-
tent of solid, non-metallic impurities in ShKh-15 and EI-736 steels decreased by
passing drops through an ANF-6 slag layer. The content of the impurities decreased
with an increase of the path length in accordance with the law of attenuation.

Card 1/2

ACCESSION NR: AP4029831

Larger impurities were extracted faster than fine impurities. The higher the impurity concentration, the more rapidly they were eliminated from the metal. The impurity content in large drops fell slower than in fine drops. The obtained regularities were qualitatively and quantitatively clear, stemming from a definite mechanism impurity extraction. It was assumed that the internal eddy movements of the impurity delivers the drops to the surface layer which remained there without returning into the metal. TITLE: Nitriding steel in a mixture of nitrogen and ammonia

SOURCE: Metallovedeniye i termicheskaya obrabotka metallov, no. 5, 1966, 49-52

TOPIC TAGS: alloy steel, metallurgic process, nitrification, nitridation, corrosion resistance/ 4Kh14N14V2M alloy steel, 25Kh18N8V2 alloy steel, Kh17G9AN4 alloy steel, 38KhMYuA alloy steel, 35KhMYuA alloy steel

ABSTRACT: The effect of nitriding the alloy steels 4Kh14N14V2M, 25Kh18N8V2, Kh17G9AN4, 38KhMYuA, and 35KhMYuA in a mixture of 20-30% ammonia and 80-70% nitrogen on the hardness, brittleness, depth, and corrosion stability of the nitride layer was investigated. The microstructure of the surface layer was also studied. The experimental results are presented in graphs and tables (see Fig. 1). Dilution of ammonia with nitrogen (up to 80% nitrogen) had no effect on the hardness or depth of the nitride layers and slightly increased the corrosion stability and fatigue limit. The results of corrosion experiments are in good agreement with the results of A. G. Andreyeva and L. Ya. Gurevich (MITOM, 1959, No. 4). It is concluded that the best nitriding results are obtained with a mixture of 20-30% ammonia and 80-70% nitrogen.

TITLE: Kinetics of spreading of a fluoride-oxide melt on solid oxides

SOURCE: Zhurnal fizicheskoy khimii, v. 40, no. 7, 1966, 1598-1603

TOPIC TAGS: calcium fluoride, aluminum oxide, fluid flow, surface tension, irreversible thermodynamics

ABSTRACT: The spreading of ANF-6 melt (70% CaF_2 , 30% Al_2O_3) on plates of Al_2O_3 , MgO , ZrO_2 , SiO_2 , and on a surface precoated with the same liquid was studied at 1480-1720°C with the aid of high-speed motion-picture photography (3000 frames per second). Two stages were observed in the spreading process. In the first stage, the liquid assumes an irregular shape with breaks in its surface. The rate v at which the plate becomes covered at this stage is independent of the surface tension of the drop, but depends on the temperature; the activation energy values indicate a viscous character of the resistance to the flow of the liquid. At a constant temperature, v depends on the plate material and decreases in the series Al_2O_3 , MgO , ZrO_2 , SiO_2 (on the precoated plate v is approximately the same as on SiO_2). The transition to the second stage is due to the action of the tension of the melt. In this stage, v is much lower than in

TITLE: γ -rays in inelastic scattering of 2.95-Mev neutrons from Al^{27}

PERIODICAL: Akademiya nauk Latvyskoy SSR. Izvestiya, no. 1 (174), 1962, 51-52

TEXT: The authors studied γ -transitions of Al^{27} with the aid of the spectra of the γ -rays forming in inelastic scattering of 2.95-Mev neutrons. The studies were made with a scintillation spectrometer, the experimental conditions were the same as in Ref. 1 (V. M. Adamov, L. Ya. Graudynya, K. A. Petrzhak, A. V. Sorokina, Izv. AN Latv. SSR, no. 5, 1961). The weight of the circular Al-scatterer was 333 g. The neutrons scattered by the Al-scatterer into the crystal interact with the NaI(Tl) crystal and bring about a γ -background. The background γ -ray spectrum was measured with an organic-glass scatterer. The number of scattering atoms was the same in aluminum and organic glass. Besides the already known γ -lines with 0.84, 1.02, and 2.25 Mev an additional line with 2.82 Mev was

Card 1/2

γ -rays in inelastic scattering ...

S/197/62/000/001/001/002
B117/B104

detected. Two more lines with the energies of 1.23 and 1.76 Mev were observed which are assigned to Al^{27} by some scientists and which are associated with the 2.75-Mev level which has hitherto not been observed in the inelastic scattering of neutrons from aluminum. These two lines are assumed to have formed as a result of the pair production caused by 2.25-Mev γ -quanta in the NaI(Tl) crystal and by the subsequent emergence of one (1.76 Mev) or two (1.23 Mev) annihilation quanta from the crystal. This assumption is confirmed by the dependence of the intensity ratio of the 1.25-, 1.76-, and 1.23-Mev lines on the crystal dimensions. A check experiment with an aluminum scatterer placed at an angle of 90° to the deuteron beam showed that the two lines (1.23 and 1.76 Mev) were present although the neutron energy was not sufficient to excite levels higher than 2.25 Mev in Al^{27} . Hence the Al^{27} spectrum has the following γ -transitions: 0.83, 1.02, 2.25, and 2.82 Mev. There are 1 figure and 10 references: 3 Soviet and 7 non-Soviet.

AUTHORS: Nikolayev, A. V., Sorokina, A. A., Maslennikova, A.S 78-1-29/43

TITLE: Cerium Extraction with Tributyl-Phosphate
(Ekstraktsiya tseriya tributilfosfatom).

PERIODICAL: Zhurnal Neorganicheskoy Khimii, 1958, Vol. 3, Nr 1,
pp. 160-164 (USSR)

ABSTRACT: After a short survey on respective literature (ref. 1-6) the authors state that diethylether is by far the best extractor (table 1). All extractors (with the exception of nitromethane) are explosive under the conditions of strong acidity. The acidity can be reduced to a great extent by salting out (table 2). The strong increase of extraction with the increase of acidity permits the conclusion that cerium-IV is extracted as a complex of the $H_2/Ce(NO_3)_6$ type. Cerium is precipitated from the ether phase with ammonium; the yield is about 90%. In the place of ammonia also hydrogen peroxide or other reducing substances can be used for extraction. In an HNO_3 milieu the reduction is made more difficult but it acquires a certain specific character (table 8). Subsequently, instructions are given for the production of pure 4-valent cerium as well as for its production from raw materials with a content of rare earths. Ce^{144} - Pr^{144} were used as radioactive indicators.

Card 1/ 3

Cerium Extraction with Tributyl-Phosphate.

78-1-29/43

From tables 3 and 4 it can be seen that rare earths did not have any salting out effect in the cerium-IV extraction with TBPh (ref. 8). An uncomplete extraction is not determined by the reduction of thorium but by its balanced distribution. The radioactive marking made possible the determination of the fact, that the reduced extraction from concentrated HNO_3 depends to a great extent on the reduction of cerium-IV as well as on the highly balanced solubility, compared with diluted acids (tables 6-8). The oxidizability of TBPh is greater during its first contact with cerium-IV (some additions are oxidized). Then the oxidizability decreases to a tolerable extent (table 7). In the water phase there is after the 1st extraction about $1/3$ of the cerium-IV present, the rest consists of cerium III. A worked out method of production for cerium from the raw material is described. Monazite residue or loparit cinders serve as such. Table 9 shows that the yield of cerium in the extract can be increased to from 93-95% by re-using the rinsing water and by a reduction of the number of washings. By means of an addition of KBrO_3 during the extraction the yield can be increased to from 96-98%. Praseodymium under the given conditions does not at all pass over to the organic phase. In the water phase there remains only its

Card 2/3

78-1-29/43

Cerium Extraction with Tributyl-Phosphate.

radioactive isotope Pr^{144} . The activity of the water phase is therefore initially high decreases, however, after from 3-4 hours ($T_{1/2} = 17,4$ minutes). There remains only a quantity of Pr^{144} equivalent to Ce^{144} (table 10). In table 7 and others the balanced activity regarding Ce^{144} and Pr^{144} is mentioned. There are 10 tables and 6 references, 2 of which are Slavic.

Kuznetsov, Doctor of Chemical Sciences, M. M. Seleznev, Candidate of Chemical Sciences, and Yu. S. Selivanov, Doctor of Chemical Sciences.

NOTE: This book is intended for chemists in general and for geochemists and analytical chemists in particular.

CONTENTS: This collection of articles consists of reports presented at the Rare Earth Elements Symposium held in June 1956 at the Institute of Chemistry and Analytical Chemistry (Inst. V. I. Vernadsky). The book may be divided into three sections: the characteristics, uses and production of rare earth elements (REE); the methods of analyzing REE; and the application of REE to various industries and REE mixtures in the glass and metallurgical industries, and their use as catalysts. The first section is devoted to the application of ion-exchange chromatography in the production of pure REE of all rare earth elements. The second section is devoted to the methods of separating REE on an industrial scale as discussed by D. I. Rykhtikov, Yu. S. Selivanov, and M. M. Seleznev. The third section is devoted to the methods of analyzing REE compounds as discussed by I. P. Alimov, R. V. Kozlovskiy, Z. P. Andreyeva, A. V. Kozlovskiy, and O. P. Kozlovskiy. Quantitative analytical methods are described by R. V. Kozlovskiy, and chemical methods of analysis by I. P. Alimov and R. V. Kozlovskiy. The determination of REE impurities in pure products and extract materials are discussed at length in three articles by A. S. Koryagin and his associates. All articles are accompanied by photographs, diagrams, tables, and bibliographic references.

TITLE:

Reciprocal Influence of Rare-earth Elements When Extracted With Tributyl Phosphate

PERIODICAL:

Doklady Akademii nauk SSSR, 1959, Vol 129, Nr 2, pp 341-344 (USSR)

ABSTRACT:

The change of extraction with concentration constitutes the simplest case of the influence mentioned in the title. The authors studied this phenomenon on neodymium, samarium, and ytterbium in nitric acid. Tributyl phosphate (TBPh) was saturated before extraction by HNO_3 . The volumetric ratio of the aqueous and organic phase amounted to 3 : 1. Nd^{147} , Sm^{153} , Yb^{175} , Y^{90} , and Ho^{166} were used for analytical purposes. The method was thoroughly dealt with in reference 8. It may be observed from table 1 that instead of a "self-salting out" (extraction increase with concentration) the opposite effect occurs in the rare-earth elements, for which the authors suggest the term "self-salting in" (samovsalivaniye). The explanation of this effect is rather simple: the limited solubility of the rare earths in the organic phase. The larger the extraction, the earlier this peculiarity of the salting-in effect must appear, as becomes manifest in such a convincing manner with

Card 1/3

Reciprocal Influence of Rare-earth Elements When
Extracted With Tributyl Phosphate

66738
SOV/20-129-2-29/66

ytterbium. Regarding Nd and Sm, the extraction stability, on the other hand, is maintained up to concentration of 5% and probably somewhat beyond (Ref 4). This difference has a great practical importance, inasmuch as the separation of the yttrium elements is more likely to be successful with lower concentration. With higher concentrations, extraction almost equals that of the cerium group, viz. becomes worse. To obtain a simple explanation of the reciprocal influence, the action of cerium earths, especially didymium, on the extraction of Nd, Sm, Y, Ho, and Yb was determined by means of radio isotopes. Table 2 shows that a 2-5% didymium concentration is not effective in all cases. 20% of didymium diminishes the extraction of all mentioned elements except Yb. The effect decreases from Nd to Ho. In this connection it occurred to the authors that the yttrium earths, but primarily the cerium earths, may exert a stronger reciprocal influence. Indicator quantities of the above mentioned isotopes were introduced into an yttrium concentrate with a composition of Nd, Pr, Sm, La, Eu, Gd, Tb, Dy, Er, Tu, Lu, and V. Even a 2% concentration of this addition has a very noticeable effect.

Card 2/3

66738

SOV/20-129-2-29/66

Reciprocal Influence of Rare-earth Elements When
Extracted With Tributyl Phosphate

Thus, the neodymium extraction is rendered lower than is the case with a 20% solution of its own salt. The ytterbium extraction is diminished to the same degree if the addition and its own salt have the same concentration. Table 3 shows this together with the values of a repeated extraction. Finally, six practical indications for extraction are given on the strength of the above rules. There are 3 tables and 8 references, 7 of which are Soviet.

TOPIC TAGS: lanthanum compound, praseodymium compound, holmium compound, yttrium compound, nitrate, chemical precipitation

ABSTRACT: An attempt is made to elucidate the role of certain kinetic factors in systems where no occlusion of impurities by the precipitate should occur in the state of equilibrium. The case of nonequilibrium systems which slowly tend toward an equilibrium is considered, and the rate of this transition for two coexisting precipitates is discussed. Specifically, the time of dissolution of nonequilibrium precipitates formed by a drop of precipitant (10.2 N ammonia solution) in 1.5 and 3% rare earth nitrate solutions was studied. This

Card 1/2

UDC: 542.65

L 36242-66

ACC NR: AP6005424

time was found to increase in the series La-Pr-Y-Ho. The effect of adding salts (5% Mg $(\text{NO}_3)_2$ and 20% NH_4NO_3 solutions) to the nitrates on the dissolution time and consumption of the reagent was also determined. The expected differences in the dissolution time of nonequilibrium rare earth precipitates were confirmed experimentally, and were used to separate La and Pr from Y and Ho. Orig. art. has: 6 tables.

TITLE: Separation of rare earth elements by fractional precipitation
with anion exchangers

SOURCE: Zhurnal prikladnoy khimii, v.38, no.11, 1965, 2410-2415

TOPIC TAGS: chemical separation, ion exchange, rare earth element

ABSTRACT: The article presents new data on the fractionation of lanthanum with an EDE-10 anion exchanger in the hydroxyl form. It also demonstrates the possibility of the efficient concentration of samarium with anion exchangers in the hydroxyl form, and the separation of lanthanum from didymium with anion exchangers in the carbonate form. The experimental data is exhibited in tabular form and shows the effect of the amount of the EDE-10 anion exchanger and the duration of the precipitation on the purity of the lanthanum oxide, its degree of extraction, and the amount of precipitated rare earth element. Experiments were carried out with a total rare earth concentration containing 20.7% didymium at room temperature. A further table shows data on the separation of

Card 1/2

UDO: 66.094.94 + 546.65

L 10984-66

ACC NR: AP6000002

lanthanum oxide approximately 98.5% pure from mixtures of rare earth elements of various compositions. It is concluded that double fractionation with the EDE-10 anion exchanger in the hydroxyl form makes it possible to obtain lanthanum oxide 99.5-99.7% pure. The experiments demonstrated the possibility of the efficient separation of other rare earth elements (for example, samarium) in the hydroxyl form by the use of anion exchangers. Using the example of the EDE-10 anion exchanger in the carbonate and oxalate forms, the article shows the possibility of the fractional separation of rare earth elements in the form of salts. TITLE: Types of atmospheric circulations and wind fields over the norther part of the Atlantic Ocean

SOURCE: Moscow. Gosudarstvennyy okeanograficheskiy institut. Trudy, no. 84, 1965. Voprosy morskoy meteorologii i okeanografii (Problems in marine meteorology and oceanography), 5-131

TOPIC TAGS: atmospheric circulation, wind direction, synoptic meteorology, ocean property, atmospheric reaction, cyclone, atmospheric pressure, wind velocity

ABSTRACT: The paper deals with the standardization of synoptic processes and wind conditions over the northern part of the Atlantic Ocean to be applied for the solution of oceanographic problems. On the basis of analysis of daily synoptic data for 55 years, the entire diversity of atmospheric circulation processes over oceans is reduced to six basic types. Data on regular seasonal changes, recurrence periods, and duration of life's cyclones are presented. Principles governing the transformation of certain cyclones into other types are developed. Peculiarities of atmospheric circulations over oceans for individual years as well as changes

Title: Free Stationary Convection Between 2 Vertical Coaxial Cylinders

Original Periodical: Uch. zapiski Molotovsk. un-t., 1955, 9, No 4, 49-60

Abstract: Study of a stationary free convection in liquid, filling a cavity between 2 long vertical coaxial circular cylinders, the walls of which are perfect heat insulators, the heat being applied from below. The hydrodynamic equations are used in the usual convection approximation. The boundary conditions are taken to correspond to heat-insulating walls and the presence of an adhesion layer around them. The effect of the end portions of the cavity are disregarded, and therefore the flow lines are considered to be parallel to the axis of the cylinders; the longitudinal temperature gradient will then be constant along the axis. A conversion is made to dimensionless quantities so as to leave in the equations only a single dimensionless parameter, equal to the product of the Grashof and Prandtl numbers. The equations can be solved only for definite values of the above parameters. After a general analysis

Title: Free Stationary Convection Between 2 Vertical Coaxial Cylinders

Original Periodical: Uch. zapiski Molotovsk. un-t., 1955, 9, No 4, 49-60

Abstract: of its spectrum, the problem is solved accurately for 2 first points of this spectrum. The corresponding distribution of the velocity and of the temperature of the liquid is obtained. The calculations are carried out approximately at various values of the ratios of the cylinder radii, and the results are given in the form of plotted equations. The first of the obtained solutions corresponds to such a motion of the liquid, in which it rises and drops in concentric layers (it rises near the internal cylinder and descends near the external cylinder or vice versa); the second solution corresponds to a motion of the liquid, in which the liquid rises on one side of any one diameter and descends on the other side. At a given ratio of cylinder radii, the first of these motions occurs at greater temperature gradients than the second. As the distance between the cylinder decreases, the temperature gradient at which the convective motion curves increases.

 TITLE: Comparative electrochemistry of stress corrosion cracking and
 pitting of stainless steel in chloride solutions
 SOURCE: Zashchita metallov, v. 2, no. 4, 1966, 416-424
 TOPIC TAGS: electrochemistry, stainless steel, steel property,
 corrosion rate, corrosion resistance, solution kinetics, chloride
 ABSTRACT: A systematic comparative study of the electrochemistry of
 corrosion cracking and pitting was made to help determine the
 relationship between the process of cracking and certain metallophysical
 factors. Studies were made on Kh18N9T steel in concentrated boiling
 MgCl₂ solutions at atmospheric pressure and in dilute chloride solutions
 heated in an autoclave to 230°. The lowest potential at which normal
 pitting occurred is more positive than the standard potentials for
 forming the chlorides of any of the component metals of the steel and
 more positive than its passivation potential. It is believed that
 activity and passivity are determined by kinetic competition in the

3

course of fitting chlorine and oxygen on the parts of the metal where the passivating film has been damaged. A high chloride concentration is not necessary for initial activation, but once solution has started, the anion concentration increases at the site. The increased anion concentration on the metal surface is then not the cause, but the result of the start of active solution. It is however a factor in localizing the solution process since repassivation of the metal by reaction with hydroxyls is obstructed. The current density of solution on a freshly cleaned surface of stainless steel is 7-10 amp/cm². Increasing the positive potential decreases the positive charge in the preelectrode layer and promotes solution. The electrochemical processes in activation and solution of the metal in pitting and corrosion cracking are identical. Rate of solution is not limited by electrochemical reactions but by the diffusion-resistance phases of the electrochemical processes. Hence cracks on the active surface of the metal do not increase in depth linearly, but more slowly, and in contrast to pitting, the initial rate of electrochemical development is almost maintained in an increasingly deep corroded crack. Increasing the Ni content should reduce cracking by affecting the dislocation structure of steel and because Ni is not passivated in concentrated chloride solutions, and would consequently delocalize active solution. High Ni steels should be examined in dilute chloride solutions in which Ni is passivated. Orig. art. has: 4 figures and 2 equations.

TITLE: A device for electromagnetic string of an 80-ton electric arc furnace

PERIODICAL: Vestnik elektropromyshlennosti, no. 4, 1962, 43-49

TEXT: Electromagnetic stirring of molten metal is achieved by means of a rotating magnetic field created by a flat, two-pole stator located below the furnace. To attain deep penetration of the magnetic field into the metal the frequency of the current should be the order of tenths of a cps. The proximity of the hot (up to 250°C) furnace bottom and the substantial linear loading of the stator create a difficult cooling problem. Air cooling and water cooling systems were constructed and their main technical and economical features compared in a table. Water cooling of the stator by passing water directly through the hollow conductors of the windings proved to be the most effective and economical cooling method, considerably saving the silicon insulating material and saving 30% of copper as compared with the air cooling system. A complete electric diagram of the stator circuit is given. Sinusoidal form of the current feeding the stator was secured by means of a negative voltage feedback network. Distribution of the magnetic field above the stator was studied by means of a Hall probe. Distribution curves are shown on a graph. Velocity of the molten metal under actual operation conditions was estimated visually and it reached 0.35 m/sec. there are 5 figures, and 2 tables.

TITLE: Comparison of methods for the phase separation of nickel chromium alloys

SOURCE: Spektral'ny*ye i khimicheskiye metody* analiza materialov (Spectral and chemical methods of materials analysis); sbornik metodik. Moscow, Izd-vo Metallurgiya, 1964, 78-83

TOPIC TAGS: nickel alloy, chromium alloy, phase separation, Alpha phase, carbide phase, electrolysis

ABSTRACT: The most widely used methods of electrolytic phase separation for heat-stable Ni-Cr alloys were investigated and compared. The baths proposed by different organizations for isolating the α -phase and carbide phase are as follows: 1. 10 g $(\text{NH}_4)_2\text{SO}_4$, 10 g citric acid, 1200 ml H_2O ; 2. 5 g $(\text{NH}_4)_2\text{SO}_4$, 15 ml HNO_3 , 35 g citric acid, 1000 ml H_2O ; 3. 3% $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$, 3.5% NaCl , 5% H_2SO_4 ; 4. 20 g CuSO_4 , 10 g sodium citrate, 5 ml H_2SO_4 , 1000 ml H_2O ; 5. anolyte: 10 g CuSO_4 , 1 g citric acid, 250 ml $\text{C}_2\text{H}_5\text{OH}$, 1000 ml H_2O ; catholyte: 10 g CuSO_4 , 10 g citric acid, 10 ml $\text{C}_2\text{H}_5\text{OH}$.

Card 1/3

L 14969-65

1000 ml H₂O; 6. 100 ml H₃PO₄, 1000 ml H₂O. The current density in all cases was 0.05-0.07 amps/cm², for 60 minutes at room temperature. The chemical analysis of the χ -phase and anode residues is described in detail. Two heat-stable Ni-Cr alloys were used: EI437B (0.037 % C, 20.57% Cr, 2.75% Ti, 0.70% Al) and EI617 (0.056% C, 15.17% Cr, 3.67% Mo, 2.00% Ti, 5.30% W, 0.21% V, 1.70 % Al) under different conditions of tempering. As shown by tabulated data, the electrolytes used are suitable for the separation of the χ -phase. The electrolyte with a smaller amount of ethyl alcohol gives a slightly decreased amount of χ -phase. Variation in the pH from 0.8 to 2.6 does not affect the total amount of χ -phase. The phase separation proceeds most favorably in electrolytes containing 30 g of citric acid during electrolysis. X-ray data show that for EI437B, a carbide of the type Ti(C,N) and Me₂₃C₆ and for EI617 a carbide of the type TiC, Me₂₃C₆ and Ni_n(W, Mo, Cr_m)C are obtained. The best results were obtained with the VIAM bath (50 ml. HCl 100 ml glycerol; 1000 ml CH₃OH, current density 0.05 amps/cm² 1 hr.) Orig. art. has: 4 tables and 1 figure.

TITLE: The Effect of Preheating the Benzine-Air Mixture on Flame Propagation Speed *yl*

PERIODICAL: V sb.: Issled. protsessov goreniya, Moscow, AN SSSR, 1958, pp. 77-80

TEXT: A study of the effect of preheating the benzine-air mixture on the flame propagation speed has been carried out with three burners of different diameter with a different mode of ignition. One burner has been used for laminar conditions and two others for turbulent conditions. The temperature of preheated mixture has varied from 17° to 227°C. Both for laminar and turbulent conditions the flame propagation speed increases with the temperature of preheating, and the increase is more intensive in the region of poorer mixtures. Experimental data *✓*

The Effect of Preheating the Benzine-Air Mixture on Flame Propagation Speed

are plotted on a diagram with the difference between absolute flame speed at a given temperature and at 0°C plotted along the Y-axis, which enables one to obtain an analytical relation between the speed of flame and the preheating temperature of the mixture. It is pointed out that the effect of initial preheating on the flame propagation speed is the same for turbulent and laminar conditions. X

TITLE: Electro-capillary Method for the Preparation of Thin Layers of Radioactive Substances on Organic Films

PERIODICAL: Pribery i tekhnika eksperimenta, 1959, Nr 5, pp 128 - 130 (USSR)

ABSTRACT: The method is based on the deposition of the substance on pure and metallised organic films by spraying the solution from the end of a capillary tube under the action of an electrical field. The system is shown schematically in Figure 1, in which 1 is an aluminium ring carrying a colloidal film ($1-2 \mu\text{g}/\text{cm}^2$) covered with a thin layer of silver (about $3 \mu\text{g}/\text{cm}^2$) and in contact with the ring. The silver layer is in electrical contact with the ring to which a negative potential is applied. The end of the capillary tube, whose diameter is 0.1 - 0.3 mm, is at about 1 - 2 cm above the film. At the top, the capillary is wider (1 mm diameter). A thin

Card1/3

Electro-capillary Method for the Preparation of Thin Layers of
Radioactive Substances on Organic Films

platinum wire 5, 0.05 mm in diameter, is let through almost to the end of the capillary tube. The experiment showed that the capillary must be very uniform and the end of the platinum wire carefully prepared. The wire is at a positive potential. In order to deposit a substance of a pure organic film, the modified installation shown in Figure 2 was used. In this figure, 1 is a glass container, 1' is a metallic electrode, 2 is the capillary, 2' is the wire, 2'' is the solution to be deposited, 3 is a glass plate, 4 is a plexiglass ring and 5 is a holder. The ring with the colloidal film is on the surface of the conducting liquid in the vessel 1. Using this apparatus, films may be obtained such that the thickness differs by 20% between the centre and the outer edges. Figure 3 shows α -particle tracks obtained in an emulsion placed in contact with some typical radioactive sources obtained in the above manner. ✓

TITLE:

The Yield of Ru^{103} and Ru^{106} in the Fission of Pu^{239} and Pu^{241} by Fast Neutrons (Vykhoody Ru^{103} i Ru^{106} pri dalenii Pu^{239} i Pu^{241} bystrykh neytronom)

PERIODICAL:

Atomaya energiya, 1959, Vol. 6, Nr. 5, pp 577-578 (USSR)

ABSTRACT:

The yields of Ru^{103} and Ru^{106} were determined by means of a relative measurement with respect to the Mo^{99} -yield. Uranium oxide (Pu^{239} -enrichment $> 90\%$) and plutonium oxide were pressed in aluminum caskets. The latter were surrounded by a 1 mm thick Cd-sheath, and the whole was packed in a finely closed aluminum cylinder. The caskets were filled with boron carbide (all-round thickness at least 2 cm). The samples were made from 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, The Yield of Ru^{105} and Ru^{106} in the Fission of
 Pu^{239} and Pu^{235} by Fast Neutrons

207/89-6-5-10/53

	$\text{Pu}^{239} (\text{a}, \text{f})$	Ru^{105}	Ru^{106}
		$5.7 \pm 1.0 \%$	$4.6 \pm 0.8 \%$
	$\text{Pu}^{235} (\text{a}, \text{f})$	$3.2 \pm 0.6 \%$	$0.71 \pm 0.12 \%$

There are 1 figure, 1 table, and 1 Soviet reference.
